ABSTRACT

Obscured AGN at high redshift likely mark the location where the first SMBHs underwent most of their growth, and could play a significant role in the cosmic BH accretion history. This crucial population of objects remains largely undetected at $z \gtrsim 4$. We propose 74 hrs of wide MIRI imaging observations to conduct a census of obscured AGN at $z=3-8$ over 95 square-arcmin in the GOODS-N and GOODS-S fields. We will observe in F1000W and F2100W, reaching 5-sigma depths of 1 micro Jy and 4 micro Jy, respectively. Our survey area is fully covered by existing NIRCам

WFSS spectroscopy and deep NIRCам imaging, allowing robust spectroscopic and photometric redshift measurements. We will identify AGN candidates using SED modeling and color selection techniques. We expect to detect 600-900 AGN candidates, including a first statistical sample of ~ 15 obscured AGN at $z > 6$. We will characterize the physical properties of these objects, measure the number density and fraction of obscured AGN at previously unexplored redshifts, and determine the contribution of obscured AGN to the cosmic BH accretion history.

OBSERVING DESCRIPTION

We will observe the GOODS-N and GOODS-S overlapping with the FRESCO footprint using the MIRI imaging mode over a total sky area of 90 arcmin^2 . In GOODS-N, we will cover the field in 30 pointings, while in GOODS-S, we will use 13 pointings to cover the regions with no existing MIRI imaging.

We will observe in two filters: F1000W and F2100W. In F1000W, we will use 65 groups with 1 integration per exposure, while in F2100W, we will use 30 groups with 9 integrations per exposure. For both filters, we will use the FASTR1 readout pattern and the CYCLING LARGE dithering pattern. We will reach an exposure time of 721 s and 3086 s for each pointing in F1000W and F2100W, achieving a point source 5-sigma depth of 1 μJy and 4 μJy , respectively. The total observing time is 44.3 hrs, with a total charged time of 73.95 hrs.
