ABSTRACT

Polycyclic aromatic hydrocarbons (PAHs) are key for maintaining the thermal and phase balance of the ISM, and important tracers of gas and star formation. PAH emission is highly sensitive to environment, especially heating by far-ultraviolet (FUV) photons. JWST has extensively studied PAH emission in FUV-rich normal star-forming disks, star-forming regions, and starbursts. However, no synthetic effort has targeted PAH emission in quiescent extremely FUV-poor regions such as galactic bulges, where the shape of the mid-IR spectral energy distribution (SED) remains poorly understood. Hence, we propose a multi-filter MIRI program to photometrically map the full mid-IR SED of 11 of the nearest face-on FUV-poor bulges and star-formation deserts. Our survey covers F560W, F1000W, F1130W, F1280W, F1500W, and F1800W, which we will combine with archival F770W and F2100W imaging to achieve complete sampling of the mid-IR SED. Our large fields of view cover both the FUV-poor bulges and adjacent star-forming disks in each target, which will serve as in-field controls. We will characterize how PAH band ratios and PAH-to-continuum ratios vary between bulges and star-forming disks, and how they vary within bulges. We will also model the observed SEDs to infer the abundance, ionization, and size of the PAHs. Comparing with ALMA mapping, we will also test the relationship between PAHs and gas in these quiescent parts of galaxies, and map the neutral ISM in bulges at unprecedented sensitivity and resolution. Our results will provide key insights into how galaxy quenching interacts with the evolution and heating of PAHs, and help interpret PAH emission from more distant quenched galaxies.

OBSERVING DESCRIPTION

We will obtain MIRI images that cover both old stellar bulges and adjacent 'normal' star-forming disks in each target. The area for imaging is chosen to match archival MIRI and NIRCам imaging (GO 2107, 3707) for each of our targets, and hence come with specific PA constraints to match archival mosaics, while making sure the observations remain schedulable and accommodate the micrometeorite avoidance zone. We will image each field in MIRI F560W, F1000W (for only 7/11 targets), F1300W (for 7/11 targets), F1280W, F1500W, and F1800W, and avoid duplications with any archival data.

We adjust exposure times according to the expected range of pixel intensities in extreme bulges for each filter given the median and 16th-84th percentile pixel intensities in archival F770W observations for each target and predictions from the latest dust models, to achieve high signal-to-noise in even the faintest parts of old bulges. We expect to detect >84% of all faint pixels in the diffuse parts of bulges at $>5\sigma$ in F560W and F1000W (expected to be our two faintest filters) and at $>8\sigma$ in all remaining MIRI filters. This results in exposure times of 277.504 seconds for F560W and F1000W, and 210.903 seconds for F1130W, F1280W, F1500W, and F1800W.

Since the galaxies generally fill the field of view of the mosaics, following the latest STScI guidance, we require MIRI Offs. During the single tile MIRI Off observations for each filter on each target, we will acquire on-target single-tile (module B) NIRCам observations to extract maximum science value for our requested telescope time.

For the parallel NIRCам observations during the required MIRI offs, we will use varying filter sets for each galaxy to fill in the near-IR SED and avoid duplication with existing NIRCам coverage -- a combination of F115W (NIRCам short, stacking multiple exposures) and F360M, F410N, F444W, and F480N (NIRCам long), which will fill in the missing near-IR SED information, as well as extracting PAH emission from the archival F335M NIRCам PAH filter. Stacking multiple exposures in NIRCам will suppress $1/f$ noise, which are expected to yield $>40\sigma$ detections of stellar continuum in bulges.

Proposal 10350 - Targets - Dust in the Deserts: Understanding PAH Emission in Quiescent Bulges and Star-formation Deserts
