ABSTRACT

A long-standing result from spectroscopic surveys is that isolated dwarf galaxies are uniformly star-forming, yet new results from a new complete sample of field dwarfs challenge this view: the quenched fraction of isolated dwarfs rises to $\sim 30\%$ below $M_{\text{star}} \sim 10^7 M_{\odot}$. These findings, consistent with predictions from recent high-resolution simulations, reveal that low-mass quenching occurs even in the field -- but when and why it happens remain unknown. We propose a JWST/NIRCam program to obtain F115W--F277W imaging for a complete, volume-limited sample of quenched, isolated dwarfs within 10 Mpc. These observations will provide (1) uniform F115W TRGB distances with $\sim 1.5\%$ precision, anchoring the precise three-dimensional location of each galaxy; and (2) quantitative, AGB-based star-formation histories that recover quenching times to ~ 1 Gyr accuracy across 0.1–13 Gyr lookback times; and (3) direct constraints on the dominant physical mechanisms -- distinguishing reionization-driven quenching, internal feedback, and dwarf–dwarf interactions. This efficient two-filter survey will transform our understanding of how the faintest galaxies evolve in isolation -- linking when low-mass galaxies shut down, how they did so, and how their histories connect to their environments.

OBSERVING DESCRIPTION

This program will obtain JWST/NIRCam imaging of 14 quenched, isolated dwarf galaxies within 10 Mpc to measure precise TRGB distances and quantitative star-formation histories. Each galaxy has an angular size of $\sim 30''$, fitting comfortably within a single NIRCam module (Module B). The observations will use simultaneous short- and long-wavelength imaging in the F115W (SW) and F277W (LW) filters. These two filters jointly enable both high-precision TRGB distances and AGB-based SFHs, while minimizing crowding and providing clean separation of RGB and AGB populations. At each target position, we will employ a 4-point INTRAMODULEBOX dither pattern with SMALL-GRID-DITHER offsets to fill detector gaps, improve sampling, and mitigate bad pixels. The DEEP2 readout mode with 3 groups per integration and one integration per exposure will be used for both filters. A total of 30 minutes of on-source integration per filter achieves $S/N \sim 15\text{--}20$ at $m_{\text{AB}} = 27$ mag, corresponding to $M_{\text{F115W}} \sim -3$ mag at 10 Mpc -- 1-2 magnitudes below the TRGB.

Including overheads, the total duration per target is ~ 91.5 minutes.

Proposal 11277 - Targets - Quenching in Isolation: JWST Star-Formation Histories of Field Dwarf Galaxies
