ABSTRACT

Most low-mass stars, including the Sun, form in stellar clusters that host massive stars which emit strong ultraviolet (UV) radiation. This radiation is thought to have a significant impact on protoplanetary disks—the birthplaces of planets. Despite the prevalence of UV radiation in these environments, its role in shaping the chemical composition of those protoplanetary disks remains poorly understood. The first JWST observations of the d203-506 disk in the Orion Nebula Cluster (ONC) suggest that UV radiation can alter the chemical makeup of protoplanetary disks. These observations revealed the presence of radicals, ions, and organic molecules indicative of UV-driven chemistry, including polycyclic aromatic hydrocarbons (PAHs) and the methyl cation (CH_3^+), marking the first detection of this molecule in such an environment. Interestingly, the mid-infrared spectrum of d203-506 differs from that of isolated protoplanetary disks, where neutral species like H_2O , HCN , CH_4 , C_2H_2 dominate. However, it is unclear how widespread the UV-driven chemical changes are across protoplanetary disks in star-forming regions. This proposal seeks to conduct a comprehensive mid-infrared spectroscopic survey of externally UV-irradiated protoplanetary disks in the ONC using the JWST's MIRI

Medium Resolution Spectrograph. Observing a large, diverse sample of disks, we aim to assess the influence of UV radiation on their chemical composition. The results will provide critical insights on the chemistry of planet-forming disks, thereby enhancing our understanding of how planetary systems, including our own Solar System, might form and evolve under such conditions.

OBSERVING DESCRIPTION

We propose to use all gratings of MIRI MRS IFU to recover the full MIRI wavelength range, applying a consistent observational strategy for each of the 77 targets in order to maintain sample uniformity and limit instrumental bias. The only existing MIRI-MRS observation of an the Orion Nebula Cluster disk (d203-506) observed as part of the ERS provided excellent results (high SNR and not affected by saturation). We therefore use the same strategy, that is a 4-point dither for extended sources, each with 1 integration, and 47 groups with the FAST1 readout. We will observe each externally UV-irradiated protoplanetary disk centered within the MIRI MRS field of view. In addition, for every 11 sources observed within 2 days, we include spectroscopic MIRI MRS off observation to subtract any undesirable emission from scattered light from the Sun or the Galactic plane, telescope emission, Zodiacal light, or instrumental signal, leading to a total of 7 off observations. To enhance the scientific yield of this program and improve the astrometric accuracy of individual MRS exposures, we will obtain simultaneous imaging with the F770W, F1000W and F1130W filters at no additional cost.
