ABSTRACT

JWST is enabling significant advances in our understanding of planet formation through measuring the composition of silicates and ices in protoplanetary disks. The same signatures that are utilized to study disks also provide diagnostic information on the surface compositions of the asteroids, which are the remnant materials left over from our Solar System's own protoplanetary disk phase. Unraveling the processes that took place

in our protoplanetary disk, and placing it in the context of our extrasolar neighbors, requires understanding the detailed composition of the asteroids. However, the majority of information available to-date is at visible to near-infrared wavelengths, which contain limited true compositional information for the majority of asteroids. We propose a comprehensive spectroscopic study of asteroid surface composition spanning 49 objects including all spectral types represented in the asteroid belt. Spectra at 5-25 microns from MIRI/MRS will reveal precise silicate composition, while spectra at 2.5-4 microns from NIRSPEC (for a subset of targets) will reveal the presence of hydrated and ammoniated minerals and organics. These data will be used to answer questions about the condensation region of objects within our protoplanetary disk, and the processes of volatile incorporation, melting, and differentiation in the planetesimals.

OBSERVING DESCRIPTION

We propose to obtain spectra of 49 main-belt asteroids, including 1-2 samples of each spectroscopic type, to assess the compositional diversity of the asteroid belt and address questions about our Solar System's early history. All targets will be observed with MIRI/MRS across its full spectral range, obtaining a SNR of 100 between 7-22 microns for all targets with the exception of a few small/faint targets that do not have brighter substitutes, where the SNR requirement is relaxed. A subset of targets will also be observed with the NIRSPEC IFU in the 235M and 395M gratings with a SNR of 50 to measure hydration, ammoniation, and organics. All exposure parameters are set so that the target will not saturate at any wavelength between 2.5-4 microns or 5-25 microns, regardless of when it is observed within the observing window set by JWST's Field of Regard. This is done by keeping groups low enough to not saturate when the object is at its brightest, and increasing integrations so that the SNR requirement is achieved even when the object is at its faintest.

Proposal 11793 - Observation 57 - The Composition and Origins of the Main-Belt Asteroids

Observation	Proposal 11793, Observation 57: 798 Ruth												Tue Jun 16 16:00:23 GMT 2026
	Diagnostic Status: Warning												
	Observing Template: MIRI Medium Resolution Spectroscopy												
Diagnostics	(Visit 57:1) Warning (Form): Overheads are provisional until the Visit Planner has been run.												
	(798 Ruth (Obs 57)) Informational (Form): The Visit Planner and Spike may produce different schedulability results.
